## THE BASICS

## What is Data Bias?

The Basics is a series exploring the concepts and individuals essential to purposeful business.

[Source](#)

## What is data bias?

Data bias occurs when data or information is limited in some way, painting an inaccurate representation of the population, or doesn't tell the full story. It has the capacity to impact individuals, businesses and even societies at large.

## 9 types of bias in data analysis and how to avoid them

Analytics can exhibit biases that affect the bottom line or incite social outrage through discrimination. It's important to address those biases before problems arise.

# BIAS in Data Collection

## Selection Bias

Selection bias happens when the data set used for training is not representative enough, not large enough or too incomplete to sufficiently train a predictive system or obtain valid descriptive statistics.

Types of selection bias –

- 1.Sampling bias:** occurs when randomization is not properly achieved during data collection.
- 2.Convergence bias:** occurs when data is not selected in a representative manner.
- 3.Participation bias:** occurs when the data is unrepresentative due to participations gaps in the data collection process.

Nice example

So let's say Apple launched a new iPhone and on the same day Samsung launched a new Galaxy Note. You send out surveys to 1000 people to collect their reviews. Now instead of randomly selecting the responses for analysis, you decide to choose the first 100 customers that responded to your survey.

This will lead to **sampling bias** since those first 100 customers are more likely to be enthusiastic about the product and are likely to provide good reviews.

Next, if you decide to collect data by surveying only Apple customers by opting out of Samsung customers, you will induce a **convergence bias** in your dataset.

Lastly, you send the survey to 500 Apple and 500 Samsung customers. 400 Apple customers respond but only 100 Samsung customers respond. Now, this dataset would be underrepresenting the Samsung customers and would count towards **participation bias**.

## Historical Bias

Historical bias occurs when data reflects historical inequalities or biases that existed during data collection, as opposed to the current context. Historical data bias occurs when socio-cultural prejudices and beliefs are mirrored into systematic processes.

### Examples

Manual (*human*) systems give certain groups of people poor credit ratings, and you're using that data to train the automatic system, the automatic system will replicate and may amplify the original system's biases.

Important to look into to prevent inequalities in prediction results

## Census

Do we « throw away » the data, or qualify it within its historical context (1996)?

## Availability Bias

Or, even if a dataset is freely available, it might be « overused » because it is costly to create another one

Datasets previously in the public domain are being locked behind paywalls or are no longer available.

Depending upon the financial backing of the modelers and the types of data, future model results might be biased toward data sets that are still available for free within the public domain.

Issues about collecting data and then having « consumers » pay for it...

# BIAS in Data Cleaning and EDA

## Measurement Bias

No contextualisation of measures

Measurement bias can occur when the accuracy or quality of the data differs across groups or when key study variables are inaccurately measured or classified.

### *Examples:*

Using CGPAs to compare students without adjusting for the fact that some courses might be more difficult, and/or some universities might have more challenging programs.

Different calibration of instruments in different medical clinics (e.g. measuring blood pressure).

## Binning Bias

Histograms group the values into intervals called bins, and the height of each bin in a histogram tells the number of points in that bin.

Bin size choice will impact the visualization and perhaps decision making.

For categorical data, we would talk of « group attribution bias »

Member-only story

### 3 Best (Often Better) Alternatives To Histograms

Avoid the most dangerous pitfall of histograms

A Histogram of Math Scores of Students

This histogram displays the distribution of math scores for a group of students. The x-axis, labeled 'Score', ranges from 0 to 100 with major grid lines every 20 units. The y-axis, labeled 'Count', ranges from 0 to 140 with major grid lines every 20 units. The data is represented by blue bars with a width of 5 units. The distribution is roughly bell-shaped, peaking at a count of approximately 145 for the score range of 65-70.

| Score Range | Count |
|-------------|-------|
| 15-20       | 2     |
| 20-25       | 5     |
| 25-30       | 10    |
| 30-35       | 15    |
| 35-40       | 25    |
| 40-45       | 40    |
| 45-50       | 60    |
| 50-55       | 85    |
| 55-60       | 105   |
| 60-65       | 125   |
| 65-70       | 145   |
| 70-75       | 115   |
| 75-80       | 105   |
| 80-85       | 75    |
| 85-90       | 60    |
| 90-95       | 35    |
| 95-100      | 25    |

A Histogram of Math Scores of Students

This histogram shows the distribution of math scores. The x-axis is labeled 'Score' and ranges from 0 to 100. The y-axis is labeled 'Count' and ranges from 0 to 250. The bars are blue and have a width of 10 units. The distribution is unimodal and slightly right-skewed, with a peak count of approximately 265 in the 60-70 score range.

| Score Range | Count |
|-------------|-------|
| 0-10        | 0     |
| 10-20       | 0     |
| 20-30       | 10    |
| 30-40       | 25    |
| 40-50       | 95    |
| 50-60       | 190   |
| 60-70       | 265   |
| 70-80       | 215   |
| 80-90       | 135   |
| 90-100      | 60    |

A Histogram of Math Scores of Students

This histogram displays the distribution of math scores. The x-axis is labeled 'Score' and ranges from 0 to 100. The y-axis is labeled 'Count' and ranges from 0 to 60. The bars are blue and have a width of 2 units. The distribution is roughly bell-shaped, peaking at a count of approximately 65 for the score range of 65-67.

| Score Range | Count |
|-------------|-------|

| 38-40       | 52    |
| 40-42       | 67    |
| 42-44       | 36    |
| 44-46       | 57    |
| 46-48       | 19    |
| 48-50       | 38    |
| 50-52       | 21    |
| 52-54       | 23    |
| 54-56       | 11    |
| 56-58       | 11    |
| 58-60       | 13    |

## Census

Too many possible  
values, hard to interpret

## Census

```
In [28]: #Grouping education
data['education'].replace('Preschool', 'Dropout', inplace=True)
data['education'].replace('10th', 'Dropout', inplace=True)
data['education'].replace('11th', 'Dropout', inplace=True)
data['education'].replace('12th', 'Dropout', inplace=True)
data['education'].replace('1st-4th', 'Dropout', inplace=True)
data['education'].replace('5th-6th', 'Dropout', inplace=True)
data['education'].replace('7th-8th', 'Dropout', inplace=True)
data['education'].replace('9th', 'Dropout', inplace=True)
data['education'].replace('HS-Grad', 'HighSchoolGrad', inplace=True)
data['education'].replace('HS-grad', 'HighSchoolGrad', inplace=True)
data['education'].replace('Some-college', 'CommunityCollege', inplace=True)
data['education'].replace('Assoc-acdm', 'CommunityCollege', inplace=True)
data['education'].replace('Assoc-voc', 'CommunityCollege', inplace=True)
data['education'].replace('Prof-school', 'Masters', inplace=True)

fig = plt.figure(figsize=(20,3))
sns.countplot(x="education", data=data)
```

Domain knowledge necessary to group categories. Can lead to « group attribution bias ».

## Outlier Bias

Averages are a great place to hide uncomfortable truths. Some data is convenient to visualize as an average, but this simple operation hides the effect of outliers and anomalies, and skews our observations.

*Examples:*

Company with most people making between 50K and 100K,  
but then a CEO making 2M.

## Imputation Bias

Replacing missing data is based on some underlying hypothesis (domain rules, distribution type, missing data type, etc). Any error in these hypotheses might lead to an inappropriate choice of imputation method.

### Example of Mode Imputation

| Customer | Age | Preferred Payment Method     |
|----------|-----|------------------------------|
| A        | 30  | Credit Card                  |
| B        | 45  | PayPal                       |
| C        | 28  | <b>Credit Card</b> (imputed) |
| D        | 50  | Credit Card                  |
| E        | 35  | Credit Card                  |
| F        | 40  | <b>Credit Card</b> (imputed) |

# BIAS in Modeling and Evaluation

Choice of algorithm,  
segmentation, evaluation

## Algorithmic Bias

Understand the data first

A prediction algorithm should be chosen with an understanding of its pros/cons.

- Some predictive approaches, e.g. probabilistic approaches, are more sensitive to prior probability on classes.
- Some approaches are more sensitive to outliers than others. (e.g. regression models)
- Some approaches require a lot more data than others.

Regression  
models

## Evaluation Bias

Testing an algorithm with a non-representative dataset leads to **evaluation bias**. Testing with a non-representative benchmarking dataset would give high overall accuracy scores, even if the algorithms were inaccurate for certain groups.

Pay attention to  
train/test...

### Facial Recognition Benchmarking Datasets

Still « results » overall will look good. Should publish results for each class.

If this is training set, discriminative features were not learned for the low-representated categories

[Source](#)

Biases from the researcher

## Confirmation bias

Also called  
experimenter's bias

A confirmation bias results when researchers choose only the data that supports their own hypothesis. Confirmation bias is found most often when evaluating results.

*"If the results tend to confirm our hypotheses, we don't question them any further,"* said Theresa Kushner, partner at Business Data Leadership, a data consulting company.

*"However, if the results don't confirm our hypotheses, we go out of our way to reevaluate the process, the data or the algorithms, thinking we must have made a mistake."*

## Overgeneralization bias

Overgeneralization occurs when you assume what you see in your dataset is :

- what you would see if you looked in any other dataset meant to assess the same information
- what you would see in the general population from which your dataset (sample) is taken

Make sure results from sample applied to the full population

This one is sometimes called « transfer bias ».

[Source](#)

# BIAS in Reporting

## Reporting bias

Reporting bias (also known as selective reporting) takes place when only a **selection of results** or outcomes are reported. It is people's tendency to under-report all the information available.

This links back to confirmation bias too

Human tendency to only report or share results that affirm our beliefs or hypotheses, also known as “positive” results. Editors, publishers, and readers are also subject to reporting bias as positive results are published, read, and cited more often. To limit reporting bias, report negative results and cite others who do, too.

Sometimes called  
« survivorship bias ».
